Groin lymph node clearance

This leaflet explains more about a groin lymph node clearance, including the benefits, risks and alternatives, and what you can expect when you come to hospital.

If you have any further questions, please speak to a doctor or nurse caring for you.

What is a groin (inguinal) lymph node clearance?
A groin lymph node clearance involves removal of all the lymph nodes and possible tumour-containing tissue from the groin region.

A system called the ‘lymphatic system’ transports a substance called ‘lymph’ around the body. Lymph is produced when liquid leaves the blood vessels and enters the surrounding tissues to help provide them with nutrients and oxygen. The lymph fluid is then collected in lymphatic vessels that run up the limbs and chest, and re-enters the bloodstream near the heart. Specialised clusters of tissue called ‘lymph nodes’ (found in the groin, armpit, abdomen, chest and neck) filter lymph travelling through the lymphatic vessels, removing bacteria and cancer cells and preventing these from spreading elsewhere in the body.

Skin cancers, such as melanoma and squamous cell carcinoma, can spread to other parts of the body by the lymphatic system. When cancer cells are filtered, they can get caught in the lymph nodes and can grow there. For example, cancer cells from a skin cancer on the foot can be transported in the lymph via lymphatic vessels to the groin where they can get caught in lymph nodes and begin to grow. They can then spread to the lymph nodes in the abdomen and chest. Cancers can also spread to other parts of the body (including the lung, brain and bone) via the bloodstream.

If the cancer has spread to your lymph nodes, lymph node clearance is usually recommended. A lymph node clearance is a major operation that aims to stop the cancer from progressing in this region.

What are the benefits of the operation?
Surgery to remove the lymph nodes in the groin will remove all the lymph nodes in the area and help to control the spread of the cancer and reduce its spread to other parts of the body.

What are the risks of the operation?
The risks of any operation relate in part to the anaesthesia and in part to the surgical procedure itself.

In most cases you will have a general anaesthetic – this means that you will be unconscious for the entire operation. You will be able to discuss this with the anaesthetist (the doctor who gives the anaesthetic) before surgery and he/she will identify the best method for your individual case. For more information about this please see our leaflet, Having an anaesthetic. If you do not have a copy, please ask us for one.
The main surgical risks are listed below. The full list of risks will be explained by the surgeon treating you.

**Very common problems (affecting approximately one in 10 patients)**
- Numbness around the scar and upper thigh (which can be permanent).
- Seroma (liquid collection at the site of operation).
- Wound rupturing or delayed wound healing.
- Lymphoedema (persistent swelling of the leg) which is due to retained lymph liquid. This can be uncomfortable and can interfere with the use of the limb. It usually occurs less than one year following the surgery but may occur later following trauma or infection in the leg. If lymphoedema develops it can be difficult to treat and requires long-term treatment with compressive stockings and specialist physiotherapy.
- Infection of the thigh.

**Common problems (affecting approximately one in 100 patients)**
- Haematoma (a collection of blood at the site of the operation).
- Neuralgia (pain in the nerves in the leg or groin).
- Poor scarring (painful or ugly) at the site of the surgical incision.

**Uncommon problems (affecting approximately one in 1,000 patients)**
- Deep vein thrombosis (blood clots in the leg veins, often referred to as DVT).
- Pulmonary embolism (blood clots in the lungs, often referred to as PE).
- Haemorrhage (heavy bleeding).
- Chest infection.

**Rare or very rare problems (affecting between one in 10,000 and one in 100,000 patients)**
- Serious damage to nerves in the leg, which may affect leg movements.
- Need for further operations, for example to clean away dead tissue at the wound site and apply a skin graft.

Rarely, in the presence of haemorrhage, a haematoma, wound healing problems or a persistent seroma, patients may need to return to theatre for a second procedure.

**Are there any alternatives?**
There are no alternative procedures. One option is not to operate. However, if left untreated, affected lymph nodes can grow in size and can put pressure on the major arteries, veins and nerves supplying the leg. This can affect the leg’s function and can cause pain. As the cancer progresses, it can enter the blood vessels and cause the overlying skin to break down.

**Giving your consent (permission)**
We want to involve you in decisions about your care and treatment. If you decide to go ahead, you will be asked to sign a consent form. This states that you agree to have the treatment and you understand what it involves.

If you would like further information about our consent process, please speak to a member of staff caring for you.
What happens at the outpatient clinic?
You will be seen by a consultant plastic surgeon or their registrar. They will ask questions, examine you, discuss the procedure and sign a consent form with you. You will need to complete some paperwork in order to book your operation, and in some cases it may be possible to give you a date for your surgery there and then. The surgeon who sees you in clinic will send a letter to your GP, informing him/her about the surgery. A copy of this will also be sent to your home address within two weeks.

Further information about the outpatient clinic is available in the leaflet, Welcome to Gassiot House Outpatient Centre. Please ask us for a copy of this leaflet if you do not have one.

What happens at the pre-operative assessment clinic?
You will usually be sent to the pre-operative assessment clinic directly from the outpatient clinic. Pre-operative assessment is an appointment where we can assess your fitness for surgery and anaesthesia.

Further information is available in our leaflet, Welcome to the pre-operative assessment clinic. Please ask us for a copy if you do not have one.

You should continue taking most medications in the days leading up to (and on) the day of your surgery. If you are taking medicines for diabetes (insulin or tablets) or are taking any antiplatelet medicines (such as aspirin or clopidogrel) or anticoagulants (such as warfarin or rivaroxaban), then these may need to be stopped temporarily or altered around the time of your procedure. You will be given further information about this during your pre-operative assessment clinic. If you are taking any complimentary medicines (such as herbal medicines), it is important to mention this at the pre-operative assessment clinic. Please also let us know if you have any allergies to any medicines.

You can eat until 2am the night before your operation and have water until 6am on the day of surgery.

What happens on the day of my surgery?
You should bring all of your regular medicines with you. Patients are usually admitted on the day of surgery, either to the Day Surgery Unit (DSU) or Surgical Admissions Lounge (SAL) at St Thomas’ Hospital. Further information about what to expect can be found in our leaflet, Surgical Admissions Lounges (SAL) and Day Surgery Units (DSU) at Guy’s and St Thomas’ hospitals. Please ask us for a copy of this leaflet if you do not have one.

Your operation will be between 8.30am to 5pm, and you may have to wait several hours before your slot in theatre. It is therefore a good idea to bring something with you to pass the time (such as a magazine or book). If you have diabetes you will be given a morning appointment.

Your surgeon will see you and mark the site of the operation with a marker pen. He/she will also talk through the operation with you again, and you will have the chance to ask questions. It is a good idea to write your questions down in advance, in case you forget them on the day.

You will also meet your anaesthetist to talk about the anaesthetic. If you are very anxious please let them know, as it may be possible for them to give you medicines to make you feel more relaxed.

If you have a good blood supply to your legs you will be given compression stockings to wear. These help to reduce your risk of developing blood clots (DVTs). Following your operation you
may also be given injections of an anticoagulant medicine, which also help to reduce the risk of developing blood clots.

You will be put to sleep in the anaesthetic room before being taken through to the operating theatre. You will not be able to feel anything (including pain) and will not remember any of the surgery.

**What happens during the operation?**
The procedure involves making an incision (cut) in the groin. This is usually a straight vertical line, which can be quite long. Major nerves, arteries, veins and other structures are protected, and then all of the surrounding tissue (including the lymph nodes) is removed. The procedure will disrupt the lymph drainage channels, causing the lymph liquid to collect in the space where the tissue has been removed. For this reason, two plastic tubes (drains) will be inserted to drain the liquid out of the body and prevent it from causing problems.

At the end of the procedure, the incision is stitched (sutured) and dressings applied. You will also be given a local anaesthetic to help reduce any pain you might experience after the surgery – this usually lasts several hours. Immediately after the operation you will be taken to a recovery area near the theatre where you will stay until you wake up. You may require additional pain relief and medication to prevent nausea from the anaesthetic. You will most likely be connected to a drip, which provides liquid until you can eat and drink. You may also have a catheter (thin tube leading to your bladder) in place until you are able to go to the toilet. Once you have fully woken up you will be taken back to the ward.

The tissue that has been removed is sent to the pathologist for examination under a microscope. This is to assess how far the cancer has spread. The results of this assessment take two weeks and will be discussed with you when you are seen in the outpatient clinic.

All patients who have had a groin lymph node clearance will also be discussed at the melanoma multidisciplinary team (MDT) meeting. This is a meeting of specialists, including the plastic surgeon, dermatologist, oncologist, radiologist and specialist skin cancer nurse. At this meeting, they will look at the tissue specimen to see how far the tumour has spread and decide if any further treatment is needed.

**What happens when I am admitted to the ward?**
Most patients will stay on Alan Apley Ward, which is on the 8th floor in the North Wing, St Thomas’ Hospital. You should expect to stay in hospital for at least two days. Following your operation, your appetite will gradually return. Once you are ready, you will be allowed to eat and drink as normal and your drip will be disconnected.

On the morning after the day of your operation, you will be seen by a team of surgeons and nurses who will examine your wound and check your health records. Some patients may also need to have blood tests.

You will still have tubes attached to drain the lymph liquid from the procedure site. The liquid usually looks bloody to start with but becomes clear and straw-coloured over time. The amount of fluid in the bottles connected to your drains will be recorded daily, and only once this falls below a certain amount can the drains be removed. The drains are normally needed for at least two to six weeks. If the drains are removed too early there can be a build up of liquid (seroma) which can be uncomfortable and may need to be removed by inserting a needle through the scar to drain off the liquid. If your drain output is high, you will be shown how to measure the level and record it for yourself at home.
Following your operation, you will be encouraged to move around to reduce the chances of developing a DVT. You will also be given a compression garment to wear (unless you have a problem with the circulation in your legs). This provides compression from your toes to above your waist and should be worn for six weeks (day and night) to reduce your chances of developing lymphoedema. You can remove it to wash and moisturise.

**What do I need to do after I go home?**

It is important to keep moving at home but you should avoid strenuous activities. You may find you are tired after the surgery and you should return to your usual activities slowly. When resting you should elevate your operated leg.

You should watch out for signs of infection, which may include increasing pain, increasing redness, swelling, oozing and fever (temperature higher than 38°C).

You can shower unless instructed not to by your consultant. Take care not to spray directly onto the wound and to gently pat (not rub) the dressings dry with a towel afterwards.

You can start driving once you feel well, alert and able to perform an emergency stop. This is usually after approximately four weeks. It is advisable to check with your insurance company before returning to driving, as this may affect your cover.

The majority of patients recover well and return to work and recreational activities about four to six weeks after the surgery. This, however, will depend on the nature of your job and the activities you participate in. The scar in your groin will improve over time and may take 18 months to settle completely. Once the wound has healed you will be given information on scar massage. You should massage and moisturise the scar for three months following the operation.

**Will I have any follow-up appointments?**

You will usually be seen in the plastics dressing clinic (PDC) one week after going home. This is so that we can check your wounds (and drains if they are still present). If we have used absorbable (dissolving) stitches, these do not need to be removed. However, non-absorbable sutures are usually removed between 10 and 14 days after your operation. Depending on the appearance of the wound, it may or may not need to be redressed.

You will also be seen in our clinic two weeks after the procedure to further check the wound and give you the results of the tissue assessment. Once your surgeon is satisfied that the operative site has healed completely, you may be discharged back to the dermatologist that originally treated you. It is likely they will follow you up for between five and ten years to make sure there is no sign of disease recurrence.
