The balance organs and dizziness

This information leaflet has been given to you to help answer some of the questions that you may have about your dizziness or balance difficulties. Several medical conditions can cause these unpleasant symptoms. This leaflet is about the most common cause of dizziness and balance difficulties – a problem within your ears. This problem may be helped by physiotherapy. If you have any questions or concerns after reading this leaflet, please talk to your physiotherapist or doctor.

What is inside your ear?

Inside each ear there is a chamber called the inner ear. This chamber has two parts:
1. The **cochlea** which is used for hearing.
2. The **balance organ** which is used for balance and steadying your vision (eyesight).

The balance organ is made of three very narrow tubes called the **semicircular canals**. These are attached to two small pouches called the **utricle** and **saccule**. Together, these structures contain fluid and tiny hairs which detect head movement and balance.

There are two balance organs – one in each ear. They work together and are often known as the **vestibular system**.
What keeps you balanced?
Your sense of balance comes from three things:
1. **Vestibular system** – the balance organs inside your ears.
2. **Eyes** – your vision gives you an image of your surroundings and how balanced you are.
3. **Body sensors** – your muscles and joints sense what position your body is in.

Your brain compares the three sources of information to make sure you keep balanced. So, if you have problems with either of your vestibular system (balance organs), eyes or body sensors, you may have balance difficulties. Dizziness, blurred vision or balance difficulties are usually caused by problems with your vestibular system.

How does the vestibular system work?
When you move your head, this movement will cause the fluid and tiny hairs inside the vestibular system to move. Signals are then passed along a special canal called the vestibular nerve to your brain. Your brain measures the movement of the hairs to quickly work out the direction and speed of your head movement. It then uses these measurements to control your body movements to help keep you balanced.

Your brain also adjusts your eye movements so that you do not have blurred vision or feel dizzy.

How does the vestibular system control your eye movements?
The two balance organs which make up your vestibular system are constantly sending signals to your brain about the position of your head. When your head is still, the signals from the right and left inner ears are equal and so your brain does not move your eyes.

When you move your head however, opposing messages are sent to your brain. This is because your two balance organs are on opposite sides of your head. When your brain gets opposing messages, it responds by moving your eyes away from the direction of the head movement.

For example, if you turn your head right, the balance organ in your right inner ear sends strong signals but your left balance organ sends weak signals. The brain uses these opposing signals to work out that your head has turned to the right. It responds by moving your eyes to the left so that your vision does not blur. This response is an important reflex which helps us keep focused on people or objects – even when our head is moving. For example, you can look at the clock while walking through the station to catch a train.
The following images show what happens to your balance organs (vestibular system) when you turn your head right:

1. **Balance Organs** send equal signals to Brain.

2. **Brain** sends equal signals to **eye muscles**.

---

Head still → Eyes stay still

1. **Balance Organs** send equal signals to Brain.

2. **Brain** sends equal signals to **eye muscles**.

---

Head turns RIGHT → Eyes turn LEFT

1. **Stronger signals** from RIGHT balance organ to brain.

2. **Brain** sends stronger signals to **LEFT** eye muscles.
What medical problems can affect your balance organs?

There are several problems that can affect one or both of your balance organs. For example, you may have been diagnosed with a viral infection, Benign Positional Vertigo or Meniere’s disease. Your physiotherapist can give you more information on these and other conditions.

You can also find more information about certain vestibular disorders by contacting the Action on Hearing Loss.
Phone: 0808 808 0123 (freephone);
Textphone: 0808 808 9000 (freephone),

Why do you feel dizzy?

If there is a problem with one of your balance organs, it will send weaker signals to your brain. This will disrupt the way in which your two balance organs usually work together. They will no longer send equal signals when your head is still and opposing signals when your head is moving. Your brain will be unable to calculate the direction, speed or angle of your head movements and this can make your brain think that your head is turning or moving when it is still.

The altered signals from your two balance organs may also cause incorrect reflex eye movements. This can cause you to feel a sense of spinning, tilting or unsteadiness. The brain also gets confused by the differing information coming from your balance organs, eyes and body sensors. This is called a sensory mismatch and it adds to your feeling of dizziness and imbalance.

What can you do to get better?

Over time, your brain will learn to cope with the altered information it gets from your vestibular system. One way it does this is by adjusting the weaker or altered signals from the affected balance organ. The two balance organs can then work together as normal. This natural process of recovery is called vestibular compensation. It will help to reduce your sensation of dizziness but it can take days, weeks or even months to do so.

To help vestibular compensation, it is good to keep moving your head and body normally and not to become less active. Sometimes dizziness does not go away completely and this is when physiotherapy may be helpful.

Your physiotherapist will encourage you to keep active and will give you exercises to do. The exercises involve movements of your eyes, head and body and are designed to cause your dizziness and unsteadiness in a safe way. By safely causing your symptoms, the exercises will help your brain learn to cope with the altered information from your balance organs. The more you practice, the easier your exercises will become. This will help your dizziness and balance problems continue to get better.
Further information

Contact us
If you have any questions or concerns about the topics covered in this leaflet, please contact your physiotherapist on 020 7188 5103, Monday to Friday from 8.30am to 5.30pm.

Patient Advice and Liaison Service (PALS) – To make comments or raise concerns about the Trust’s services, please contact PALS. Ask a member of staff to direct you to the PALS office or:
t: 020 7188 8801 at St Thomas’ t: 020 7188 8803 at Guy’s e: pals@gstt.nhs.uk

Knowledge & Information Centre (KIC) – For more information about health conditions, support groups and local services, or to search the internet and send emails, please visit the KIC on the Ground Floor, North Wing, St Thomas’ Hospital.
t: 020 7188 3416

Language support services – If you need an interpreter or information about your care in a different language or format, please get in touch using the following contact details.
t: 020 7188 8815 fax: 020 7188 5953

NHS Direct - Offers health information and advice from specially trained nurses over the phone 24 hours a day.
t: 0845 464 7 w: www.nhsdirect.nhs.uk

NHS Choices – Provides online information and guidance on all aspects of health and healthcare, to help you make choices about your health.
